Acknowledgements

We wish to thank the captains and crews of the R/V *Knorr* and the R/V *Endeavor* for their help during these cruises. The Scripps Oceanographic Data Facility (SIO/ODF) kindly provided personnel and equipment to collect and process the deep CTD and salinity data. J. Costello and L. Lopez were the CTD technicians on the two cruises, respectively, and R. Williams, F. Delahoyde, and M. Johnson worked up the deep data and performed the calibrations. W. Hess (APL) provided analysis and plotting software. B. Paisley (APL) performed preliminary processing.

The Greenland Sea Project is sponsored by the National Science Foundation (NSF Grant DPP-8518643) and the Office of Naval Research (ONR Grant N00014-86-G-0150). The Moving Ship Tomography Project is sponsored by the Office of Naval Research (ONR Contract N00014-87-K-0217) and the Office of Naval Technology (ONT Contract N00014-87-K-0760).

ABSTRACT

Profile data from two cruises in the Greenland Sea are presented. During the first cruise in September - October 1988, there were 6 deep CTD stations occupied and 161 shallow CTD, XBT, and XSV drops made. During the second cruise in August - September 1989, there were 6 deep CTD stations occupied and 299 shallow CTD, XBT, and XSV drops made.

1. INTRODUCTION

The profile data presented in this report were taken in support of two projects. The goals of the first, the Greenland Sea Project (GSP) tomography experiment, were (1) to study the processes that occur during convection and ventilation of the deep waters in the Greenland Sea, and (2) to study the dynamics of the wind-driven Greenland Sea gyre. The goals of the Moving Ship Tomography (MST) project are (1) to determine the precision with which the ocean mesoscale sound speed field can be measured by moving ship tomography, and (2) to study mesoscale eddy kinematics and dynamics. The MST project made use of the acoustic sources installed for GSP to perform engineering tests.

The acoustic moorings were installed (Figure 1.1), and deep CTD stations were occupied during the first part of the R/V *Knorr* cruise in September 1988. During the last eight days of the cruise, MST tests were conducted (MST88). XBT and/or XSV measurements (760 m and 850 m, respectively) were made at approximately 13 km spacing along all but 3 of the 15 transmission paths between the transceiver moorings (Figure 1.2).

The MST89 cruise dates of 3–16 August 1989 encompassed Leg 1 of EN200. A CTD profile was taken to a depth of 135 m (the base of the deployed acoustic array) at each of the 54 acoustic stations. Five sections, from moorings 1–3, 1–4, 1–5, 3–4, and 3–5, were made with XBTs deployed every 6 km and an XSV deployed every 30 km (Figure 1.3). Six deep CTD stations were occupied during Leg 3, from 5 to 10 September.

2. INSTRUMENTATION

A Sea-Bird Electronics (SBE) Model 9-02 underwater CTD unit, serial number 91685, was used for both cruises. The underwater unit contained the following sensors: dual temperature sensors (model SBE-3-02/F, serial numbers 843, primary, and 844, secondary), dual conductivity sensors (model SBE-4-02/O, serial numbers 484, primary, and 485, secondary), and a submersible pump (model SBE-5-02, serial number 128). The pump increased the flushing speed of water through the conductivity sensors to improve their dynamic response. Two Paroscientific Digiquartz pressure sensors were used; shallow casts were made using a 0–3000 psi (0–2000 m) sensor (model SBE 12-03/T, serial number 33273), and deep casts were made using a 0–10,000 psi (0–6000 m) sensor (model SBE 12-02/T, serial number 26451). The CTD deck unit (model SBE 11, serial number 111685) was set to average 24 scans per second to produce one output scan per second. A personal computer was used both to control the deck unit and to acquire the data.

A General Oceanics rosette sampler with twelve 1.5-l Niskin bottles was used to collect water samples during the deep CTD casts. In 1988, the length of wire limited the maximum cast depth to about 2900 m.

XBT and XSV data were acquired using a Sippican Mark 9 system. The XBT probes were Sippican model T-7, 760 m, and the XSV probes were Sippican model XSV-02, 850 m.

For the purposes of these profile data, positions were obtained from LORAN-C instruments. For the 1988 cruise, data from the ship's Northstar 6000 were used. For the 1989 cruise, data from both the ship's Northstar 6000 and APL's Northstar 800 were used, the former substituting if the latter had a gap. For the second cruise, a simple filtering procedure was used to clean up the data (there were some lane jumps) before positions were assigned to the XBT and XSV profiles based on time (personal communication, B. Cornuelle and P. Sutton). These positions are expected to be accurate to within 1 km.

3. CALIBRATION AND DATA PROCESSING

Calibrations of the CTD sensors were performed on four different occasions. SBE calibrated all sensors at the Northwest Calibration Center (NWCC) in April 1988 and December 1990. Scripps Technical Services at SIO calibrated them in February 1989 and in June 1990. The deep CTD data reported here for 1988 and 1989 use the SIO calibrations of 1989 and 1990, respectively. The shallow CTD data from both 1988 and 1989 use the SIO calibration of February 1989. The differences are discussed below.

No attempt has been made to correct for the response of the temperature and conductivity sensors; indeed, no correction is possible since the data were averaged once per second in the deck unit. The sound speed algorithm of Del Grosso has been used to convert temperature, salinity, and depth (pressure) to sound speed.

There has been very little editing of the profiles reported here. The surface value has been set equal to the value at 5 m for the XBT and XSV profiles. Some XBT and XSV profiles have been thrown out because of obvious failure of the probe. The standard Sippican equations in Sippican software were used to convert raw data to engineering units. The deep CTD data for both years were gridded to 2-m intervals; the shallow CTD data were gridded to 1-m intervals. The XBT and XSV data were gridded to standard depths: 0, 5, 10, ...50, 60, 70, ...200, 220, 240 ...740, ...800 m.

4. DISCUSSION OF RESULTS

Logs showing times and positions for the various profiles are presented in Appendices A and B for 1988 and 1989, respectively. Each profile is plotted in Appendices C and D. In this section, averaged and overlaid profiles are presented with a brief discussion.

All the data are available on cartridge tape (UNIX) and/or floppy disks (PCs), in addition to being available from the National Ocean Data Center (NODC).

4.1 1988 Data

CTD Data

In early September, a warm (5°C) surface layer was over the entire area; by the end of the cruise in early October, winter cooling had commenced.

Figure 4.1 shows the average of the six deep CTD profiles, and Figure 4.2 shows the individual casts plotted on top of each other so one can see the variability that is present. There is evidence of occasional salinity spiking. One profile appears anomalously warm and salty between the surface and 1000 m relative to the others. Figure 4.3 shows the T-S scatter plot from these data.

To see the possible effects of different calibrations, the differences (SBE April 1988 – SIO/ODF February 1989) between variables are plotted in Figures 4.4a and 4.4b for cast 001. Below about 40 m, the temperature difference is within 0.001°C while salinity, sound speed, and density (σ_0) are within 0.01 ppt, 0.01 m/s, and 0.02 σ_0 units, respectively. Above 40 m, salinity spiking is much more pronounced.

Figure 4.5 shows the average of the 21 shallow CTD casts made as part of the deployment of the acoustic array for MST. It is clear that salinity for the most part controls the density. The negative density gradient at the surface is undoubtedly an artifact of the averaging and/or the sensitivity of density to (suspect) salinity measurements. Figures 4.6a–4.6d show the individual profiles. Within the mixed layer and down to 125 m,

there is about 2°C peak-to-peak variation in temperature and a 10 m/s variation in sound speed. Salinity varies about 1.5 ppt in the mixed layer (to 30 m) and about 0.1 ppt at 100 m. Density follows this trend, varying 1.5 σ_0 units in the mixed layer and 0.1 σ_0 units at 100 m.

XBT and XSV Data

Figure 4.7 shows the average temperature profile as obtained from the 118 drops shown in Figure 4.8. The values and variation are about the same as for the CTD data. There are some anomalously large temperatures at about 30 m depth. Figures 4.9 and 4.10 show similar data from the 24 XSV drops. The small peak in temperature and sound speed at ~30 m shows up in all the data and is consistent with the slight salinity minimum.

4.2 1989 Data

CTD Data

The deep CTD data from 1989 (Figures 4.11–4.13) look quite similar to the data from 1988. In one profile there appears to be a salinity-compensated warm feature between 100 m and 1000 m. There is somewhat less scatter in the T-S relation.

The shallow CTD data from 1989 show warmer water and a shallower mixed layer, not surprising since the 1989 data were taken in August while the 1988 data were taken in late September.

XBT and XSV Data

The XBT and XSV data for 1989 do not show the surface minimum and the subsurface maximum that were present in 1988.

APPENDIX C

Plots of Raw Profile Data for the 1988 Cruise

The plots of the raw profile data presented in this appendix are ordered as follows:

Deep CTD casts (labeled GSP Deployment CTD cast #,
where # is the cast number given in the log)

Shallow CTD casts (labeled 1988 MST: CTD cast #)

Waterfall plots of XBT profiles (labeled MST 88 XBT Drops # - #)

Waterfall plots of XSV profiles (labeled MST88 XSV Drops # - #).

For the CTD plots, the key is as follows:

Temperature = thin line

Salinity = heavy line,

Sound speed = medium line

Density (σ_0) = dashed line.

For the XBT waterfall plots, the profiles are offset by 0.5°C.

For the XSV waterfall plots, the profiles are offset by 10 m/s.

APPENDIX D

Plots of Raw Profile Data for the 1989 Cruise

The plots of the raw profile data presented in this appendix are ordered as follows:

Deep CTD casts (labeled GSP Deployment CTD cast #,
where # is the cast number given in the log)

Shallow CTD casts (labeled 1989 MST: CTD cast #)

Waterfall plots of XBT profiles (labeled MST 89 XBT Drops #—#)

Waterfall plots of XSV profiles (labeled MST89 XSV.Drops #—#).

For the CTD plots, the key is as follows:

Temperature = thin line

Salinity = heavy line

Sound speed = medium line

Density (σ_0) = dashed line.

For the XBT waterfall plots, the profiles are offset by 0.5°C.

For the XSV waterfall plots, the profiles are offset by 10 m/s.
